

LOCAL HOMEOMORPHISMS VIA ULTRAFILTER CONVERGENCE

MARIA MANUEL CLEMENTINO, DIRK HOFMANN, AND GEORGE JANELIDZE

ABSTRACT. Using the ultrafilter-convergence description of topological spaces, we generalize Janelidze-Sobral characterization of local homeomorphisms between finite topological spaces, showing that local homeomorphisms are the pullback-stable discrete fibrations.

INTRODUCTION

In this paper we complete the study of some special classes of continuous maps using convergence (see [7, 6, 2, 3, 4]). The recent interest in this had as starting point the Janelidze-Sobral paper [6], where the authors presented characterizations of proper, perfect, open, triquotient maps and local homeomorphisms between finite topological spaces using point convergence. This motivated the study of the infinite version of these characterizations, successfully established in [3], with the exception of local homeomorphisms. This paper fills the remaining gap.

In [6], interpreting a finite topological space as a category via its point-convergence description, it is proved that:

Theorem I. *A continuous map between finite topological spaces is a local homeomorphism if and only if it is a discrete fibration.*

For infinite spaces, replacing point convergence by ultrafilter convergence, local homeomorphisms turn out to be the pullback-stable discrete fibrations. Indeed, in this paper we present an example of a discrete fibration which is not a local homeomorphism, and we prove:

Theorem II. *A continuous map between topological spaces is a local homeomorphism if and only if it is a pullback-stable discrete fibration.*

Note that, since general (infinite) topological spaces cannot be viewed as categories, what we call the discrete fibrations of topological spaces has to be

defined; however our definition (see Section 2) is a straightforward imitation of the categorical one: *just interpret arrows as convergence*.

We also introduce the notion of a λ -space (where λ is a cardinal number), and show that pullback stability comes for free whenever the domain of the given map is a λ -space. This is important because amongst the λ -spaces we have both *Alexandrov* and *first countable T_1 -spaces*, that is, we have the “strange spaces” we generalized and the spaces that occur in classical geometry at the same time.

1. LOCAL HOMEOMORPHISMS AND OPEN MAPS

We recall that a *local homeomorphism* is a continuous map $f : X \rightarrow Y$ which is locally a homeomorphism; that is, each $x \in X$ has an open neighbourhood U such that $f(U)$ is open and the map $f|_U : U \rightarrow f(U)$ is a homeomorphism.

It is well-known that:

Proposition 1. (1) *For a continuous map $f : X \rightarrow Y$, consider the following commutative diagram, where the square is a pullback:*

$$\begin{array}{ccccc}
 X & \xrightarrow{1_X} & X & & X \\
 \delta_f \searrow & & \downarrow \pi_2 & & \downarrow f \\
 X & \times_Y & X & \xrightarrow{\pi_2} & X \\
 \downarrow \pi_1 & & \downarrow \pi_1 & & \downarrow f \\
 X & \xrightarrow{1_X} & X & \xrightarrow{f} & Y
 \end{array} \tag{A}$$

The following assertions are equivalent:

- (a) f is a local homeomorphism;
 - (b) f is open and locally injective;
 - (c) both f and δ_f are open maps.
- (2) *Local homeomorphisms are pullback-stable.*

The following results can be found in [3]:

Theorem 1. (1) *A continuous map $f : X \rightarrow Y$ is open if and only if, for each $x \in X$ and each ultrafilter η with $\eta \rightarrow f(x)$ in Y , there exists an ultrafilter \mathfrak{x} such that $\mathfrak{x} \rightarrow x$ in X and $f(\mathfrak{x}) = \eta$; we display this as*

$$\begin{array}{ccc}
 X & & \mathfrak{x} \dashrightarrow x \\
 f \downarrow & & \downarrow \quad \downarrow \\
 Y & & \eta \longrightarrow f(x)
 \end{array} \tag{B}$$

- (2) *If $f : X \rightarrow Y$ is a local homeomorphism, then the ultrafilter \mathfrak{x} in (B) is unique.*

2. DISCRETE FIBRATIONS

According to what we said in the Introduction, one can imitate many categorical notions in topology simply by replacing arrows=morphisms with arrows representing ultrafilter convergence. In particular the continuous maps of topological spaces will then come up as an imitation of functors, and then the existence and uniqueness of liftings displayed in (B) will come up as an imitation of the discrete-fibration condition. Hence we define a *discrete fibration* of topological spaces as a continuous map $f : X \rightarrow Y$ with

$$\begin{array}{ccc} X & & (\exists!) \mathfrak{r} \dashrightarrow x \\ f \downarrow & & \downarrow \quad \downarrow \\ Y & & \eta \longrightarrow f(x), \end{array}$$

which means that, for each $x \in X$ and each ultrafilter η with $\eta \rightarrow f(x)$ in Y , there exists a unique ultrafilter \mathfrak{r} such that $\mathfrak{r} \rightarrow x$ in X and $f(\mathfrak{r}) = \eta$.

The class of all discrete fibrations of topological spaces will be denoted by \mathcal{H} .

For each topological space X , we denote by $\text{Conv}(X)$ the set of pairs (\mathfrak{r}, x) , where x is a point, and \mathfrak{r} an ultrafilter converging to x in X . The set $\text{Conv}(X)$ has a canonical, but not necessarily topological, convergence structure, giving rise to a functor Ult studied in [3]; however we will not use that structure here. Each continuous map $f : X \rightarrow Y$ induces a map $\text{Conv}(f) : \text{Conv}(X) \rightarrow \text{Conv}(Y)$ with $(\mathfrak{r}, x) \mapsto (f(\mathfrak{r}), f(x))$. Clearly, a continuous map $f : X \rightarrow Y$ belongs to \mathcal{H} if and only if the diagram

$$\begin{array}{ccc} \text{Conv}(X) & \xrightarrow{\text{Conv}(f)} & \text{Conv}(Y) \\ \pi_X \downarrow & & \downarrow \pi_Y \\ X & \xrightarrow{f} & Y \end{array}$$

is a pullback in **Set**; here and below π_X and π_Y are the projection maps.

Using this formulation it is easy to prove that:

- Proposition 2.** (1) *Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be continuous maps. If $g \cdot f$ and g are in \mathcal{H} , then so is f .*
 (2) *Given a pullback diagram*

$$\begin{array}{ccc} W & \xrightarrow{k} & X \\ h \downarrow & & \downarrow f \\ Z & \xrightarrow{g} & Y \end{array}$$

*in **Top**, such that k is an injective map, if f is in \mathcal{H} then so is h . In particular, \mathcal{H} is stable under pullbacks along injective continuous maps.*

Proof. To prove (1), consider the following commutative diagram in **Set**

$$\begin{array}{ccccc} \text{Conv}(X) & \xrightarrow{\text{Conv}(f)} & \text{Conv}(Y) & \xrightarrow{\text{Conv}(g)} & \text{Conv}(Z) \\ \pi_X \downarrow & & \pi_Y \downarrow & & \downarrow \pi_Z \\ X & \xrightarrow{f} & Y & \xrightarrow{g} & Z. \end{array}$$

Since, by hypothesis, the outer diagram and the right-hand square are pullback diagrams, also the left-hand square is a pullback diagram, and the result follows.

(2): We only need to show that, in the commutative diagram

$$\begin{array}{ccccc} & & W & \xrightarrow{k} & X \\ & \nearrow \pi_W & \downarrow \text{Conv}(k) & \nearrow \pi_X & \downarrow f \\ \text{Conv}(W) & \xrightarrow{\quad} & \text{Conv}(X) & & \\ \text{Conv}(h) \downarrow & & h \downarrow & & \downarrow \text{Conv}(f) \\ & \nearrow \pi_Z & Z & \xrightarrow{g} & Y \\ \text{Conv}(Z) & \xrightarrow{\text{Conv}(g)} & \text{Conv}(Y) & & \nearrow \pi_Y \end{array}$$

the maps $\pi_W : \text{Conv}(W) \rightarrow W$ and $\text{Conv}(h) : \text{Conv}(W) \rightarrow \text{Conv}(Z)$ are jointly monic. This is immediate since π_X and $\text{Conv}(f)$ are jointly monic, because f is in \mathcal{H} and $\text{Conv}(k)$ is injective (since k is) by hypothesis. \square

Discrete fibrations do not need to be local homeomorphisms, as the following example shows:

Example. Let \mathfrak{x} be a non-principal ultrafilter on the set \mathbb{N} of natural numbers and consider \mathbb{N} endowed with the topology $\{A \subseteq \mathbb{N} \mid 0 \in A \Rightarrow A \in \mathfrak{x}\}$. Consider the Sierpinski space $\{0, 1\}$, with the non-trivial open subset $\{1\}$. Let

$$f : \mathbb{N} \rightarrow \{0, 1\} \\ n \mapsto \begin{cases} 0 & \text{if } n = 0, \\ 1 & \text{otherwise.} \end{cases}$$

Then f is not a local homeomorphism since it is not injective on any neighbourhood of 0. However it belongs clearly to \mathcal{H} : if $n \in \mathbb{N} \setminus \{0\}$ and $\eta \rightarrow f(n) = 1$ in $\{0, 1\}$, then $\eta = \dot{1}$ (=the ultrafilter generated by $\{1\}$) and so \dot{n} is the unique ultrafilter in \mathbb{N} with image η converging to n ; if $n = 0$, we have two possibilities: $\dot{0} \rightarrow 0$, whose unique lifting is $\dot{0}$, and $\dot{1} \rightarrow 0$, whose unique lifting is \mathfrak{x} .

3. THE CHARACTERIZATION THEOREM

We consider again Diagram (A).

Theorem 2. *For a continuous map $f : X \rightarrow Y$, the following conditions are equivalent:*

- (i) f is a local homeomorphism;

- (ii) f is stably in \mathcal{H} ;
- (iii) both f and $\pi_1 : X \times_Y X \rightarrow X$ belong to \mathcal{H} ;
- (iv) both f and δ_f belong to \mathcal{H} ;
- (v) for each indiscrete space Z , $f \times 1_Z : X \times Z \rightarrow Y \times Z$ belongs to \mathcal{H} ;
- (vi) both f and $f \times 1_{X'} : X \times X' \rightarrow Y \times X'$ belong to \mathcal{H} , whenever X' is the indiscrete space with the underlying set of X .

Proof. (i) \Rightarrow (ii) follows from Proposition 1. (ii) \Rightarrow (iii) is trivial, while to prove (iii) \Rightarrow (iv) we use Proposition 2 and the equality $\pi_1 \cdot \delta_f = 1_X$. From (iv) it follows that both f and δ_f are open maps, hence f is a local homeomorphism, by Proposition 1. Therefore the first four conditions are equivalent. It is also clear that (ii) \Rightarrow (v) \Rightarrow (vi), and so to complete the proof it suffices to show that (vi) implies (iii). For that, we observe that the pullback of f along f can be decomposed into two pullbacks as below, where $\langle f, 1 \rangle$ is injective; afterwards we apply Proposition 2 to the left-hand pullback:

$$\begin{array}{ccccc}
 & & \pi_2 & & \\
 & & \curvearrowright & & \\
 X \times_Y X & \longrightarrow & X \times X' & \xrightarrow{p_X} & X \\
 \pi_1 \downarrow & & \downarrow f \times 1_{X'} & & \downarrow f \\
 X & \xrightarrow{\langle f, 1 \rangle} & Y \times X' & \xrightarrow{p_Y} & Y \\
 & & \curvearrowleft & & \\
 & & f & &
 \end{array}$$

□

4. WHEN LOCAL HOMEOMORPHISMS AND DISCRETE FIBRATIONS COINCIDE

The equivalence between local homeomorphisms and discrete fibrations obtained by Janelidze and Sobral in [6] for finite topological spaces can be obtained in a more general setting that includes Alexandrov spaces and first countable T_1 -spaces. To present it, we introduce λ -spaces, for λ a cardinal number: these are the topological spaces X such that:

- (a) the character of X is at most λ (i.e. every neighbourhood filter has a base with cardinality at most λ);
- (b) each subset of X with cardinality less than λ is closed.

The 0-spaces are the indiscrete spaces, the 1-spaces (n -spaces for each finite cardinal n , respect.) are the Alexandrov (T_1 -)spaces, while the \aleph_0 -spaces are the first countable T_1 -spaces. Assuming CH, an example of an \aleph_1 -space is the line \mathbb{R} with the cocountable topology.

Theorem 3. *If X is a λ -space, then a continuous map $f : X \rightarrow Y$ is a local homeomorphism if and only if it is a discrete fibration.*

Proof. We only have to check that $f : X \rightarrow Y$ is locally injective whenever it is a discrete fibration. In order to do that, we assume that f is not locally injective, that is

$$\exists x \in X : \forall U \in \mathcal{O}(x) \exists a, b \in U : a \neq b \text{ and } f(a) = f(b),$$

where $\mathcal{O}(x)$ denotes the set of open neighbourhoods of x . Then there are two possibilities, which we will consider separately:

(a) We have

$$\forall U \in \mathcal{O}(x) \exists a_U \in U \setminus \{x\} : f(a_U) = f(x).$$

Consider an ultrafilter \mathfrak{a} in X such that $\mathfrak{a} \supseteq \mathcal{O}(x)$ and $\{a_U; U \in \mathcal{O}(x)\} \in \mathfrak{a}$. By construction it converges to x and its image by f is $f(x)$. Since $f(x)$ may also be lifted by the ultrafilter $\mathfrak{b} = \dot{x} \neq \mathfrak{a}$, the assumption of the Theorem fails.

(b) If there is a neighbourhood V of x such that $f(x) \notin f(V \setminus \{x\})$, we have

$$\forall U \in \mathcal{O}(x) \exists a, b \in U : a \neq b \text{ and } f(a) = f(b) \neq f(x).$$

The result is obvious for $\lambda = 0$, and so we consider now $\lambda \neq 0$. For each neighbourhood U of x , consider the set $A := \{\{a, b\} \subseteq U \mid b \neq a \text{ and } f(a) = f(b) \neq f(x)\}$. Since, by the condition above, $U \setminus \bigcup A$ is not neighbourhood of x , $\bigcup A$ is not closed, hence its cardinality is at least λ . For λ finite we may even conclude that $\bigcup A$ is infinite. Hence, for any $\lambda \neq 0$, A has cardinality at least λ .

Let $\{U_\alpha; \alpha \in \lambda\}$ be a neighbourhood base of x . We may choose two disjoint injective families $(a_\alpha)_{\alpha \in \lambda}$ and $(b_\alpha)_{\alpha \in \lambda}$ (that is, two injective maps $a, b : \lambda \rightarrow X$ with disjoint images) such that both a_α and b_α belong to U_α and $f(a_\alpha) = f(b_\alpha) \neq f(x)$ for each $\alpha \in \lambda$. Let \mathfrak{a} be an ultrafilter converging to x and to which $\{a_\alpha; \alpha \in \lambda\}$ belongs. The ultrafilter \mathfrak{b} obtained by replacing in \mathfrak{a} each a_α with b_α is different from \mathfrak{a} , although $f(\mathfrak{b}) = f(\mathfrak{a})$ and both converge to x . \square

Remarks. (1) The part (a) of our proof does not use λ and is obviously valid for arbitrary spaces. In fact this shows that every discrete fibration is an open map with discrete fibres. Therefore the class of discrete fibrations, which itself is not pullback-stable, is however strictly between two pullback-stable classes, that are not too far from each other – namely of local homeomorphisms and of open maps with discrete fibres.

(2) Is there a reasonable simultaneous generalization of the notions of a discrete fibration for categories and for topological spaces? Most probably this question has several good answers; a straightforward one would be just to copy both (=any of the two) definitions to T -categories in the sense of Burroni [1]. One could also try the far more general context of Clementino-Tholen [5].
